BeSS report Materiel & Method

This report is automatically generated by a python script available here:

<https://github.com/Vdesnoux/pyBeSSVO>

For each star, we compare the most recent spectrum available in the BeSS database with the earliest spectrum obtained prior to the month of the report. An algorithm has been developed to classify the spectral evolution according to three criteria: (i) changes in the line profile morphology, (ii) relative or absolute variations in the equivalent width (EW), and (iii) the sum of the absolute flux differences between the two spectra and a chi2 test.

Prior to the computation of these metrics, a set of pre-processing steps is applied:

- Continuum normalization of the spectra on the 6610-6620 Å interval
- Resampling to a uniform wavelength grid with a step of 0.1 Å per pixel
- Restriction of the spectral range to the 6540–6586 Å interval
- Removal of telluric absorption features
- Noise reduction using a Savitzky–Golay filter with a 3 Å equivalent kernel
- Correction for heliocentric velocity based on the BSS_RQVH keyword.
