BeSS report Materiel & Method

This report is automatically generated by a python script available here:

<https://github.com/Vdesnoux/pyBeSSVO>

For each star, we compare the last spectrum from BeSS database to the first spectrum found before the month of the report. An algorithm is designed to classify the spectra evolutions based on 3 criteria: form change, percentage or difference of EW and the sum of the absolute value of the differences of the two spectra.

A set of pre-processing is applied before the metrics are computed:

- normalization
- resampling to 0.1 ang/pixels
- crop to the 6540 – 6586 angström region
- removal of the telluric lines
- noise reduction with Savitzky–Golay filter
- heliocentric speed correction based on the BSS_RQVH keyword
